SUMMARY

Background. Increased plantar pressure when walking is among the pathogenesis of diabetic foot ulceration. Contractured Achilles tendon will biomechanically result in increased plantar pressure. In this study, we summarize the correlation between increased transforming growth factor β1 (TGF-β1) expression and the development of Achilles tendon contracture in diabetic foot patients.

Methods. Thirty diabetic foot patients with indication for surgery were enrolled to this study and divided to two groups. Case group consisted of patients presenting Achilles tendon contracture, in contrary with control group. During surgery, the specimens of Achilles tendon were taken and analysed semi-quantitatively by immunohistochemical (IHC) examination. Achilles contracture as a dependent variable was concluded from physical examination, and later by histological findings.

Results. IHC revealed that the positive TGF-β1 expressions were found in all case and control group cases, respectively. There were different results between both groups regarding the expression strength, specifically 2/15 vs 8/15 for + 3 result, 10/15 vs 6/15 for + 2 result, and 3/15 vs 1/15 for + 1 result. Linear regression analysis showed significant result (p < 0.05) of age and TGF-β1 expressions as the determinants of Achilles tendon contracture, while the results for sex, body mass index (BMI), and HbA1c were insignificant.

Conclusions. Chronic hyperglycemia was thought to be one of the etiology of Achilles tendon contracture through the cascade involving the advanced glycation end products (AGEs) accumulation. However, these results suggested that the HbA1c level is not a sole determinant, and TGF-β1 should be considered as a contributing factor for Achilles tendon contracture during the development of diabetic foot ulcerations.

Achilles tendon; contracture; diabetes; immunohistochemistry; TGF-β1.
Tendon imbalance, especially due to Achilles and gastrocnemius-soleus tightness, may cause an increased stress in the forefoot. Increased stress in the forefoot can cause a callus, followed by a forefoot ulcer (4). Prior comparison between diabetic and nondiabetic patients suggests that equinus may be more prevalent in diabetic patients. Coombes et al. had also concluded that Achilles tendon from individuals with type 2 diabetes were thicker compared to inactive individuals without diabetes (5). Nonetheless, these data are insufficient to prove causality and lack the required power to prove or disprove these relationship (4, 6).

Hyperglycemia in diabetic patients is responsible for the presence of high levels of nonenzymatically produced advanced glycation end-products (AGEs) in patients with diabetes. AGEs play an important role in cell signaling by interacting with specific receptors that link to the activation of adhesion molecules, proinflammatory cytokines and growth factors, thus contributing to the pathogenesis of diabetic complications (7). AGEs are able to stimulate directly the production of extracellular matrix (ECM) (8). However, despite the recognized importance of AGEs in the development of age and diabetes related conditions, there are still several important open questions regarding their role in the onset and progression of connective tissue disease (9). Why contracture is not commonly found in all diabetic patients is not yet fully understood. Other than hyperglycemia, factors that regulate ECM formation include multiple forms of growth factor such as transforming growth factor-beta (TGF-β). The important role of growth factors in the pathogenesis of diabetic long-term complications was suggested by their increased concentrations in target tissues. An excess of growth factor is implicated in tissue where fibrosis predominates, whereas a lack of growth factors occurs in diabetic neuropathy and wound healing (7). Among the TGF-β isofoms, TGF-β1 has been known to promote wound healing and also fibrosis (10, 11).

In our literature review, there is still insufficient study on pathogenesis of diabetic ulcer focusing on the development of equinus due to contracture of Achilles tendon. In this study, we evaluated immunohistochemical expression of TGF-β1 in Achilles tendon tissue by comparing between contractured and non-contracted tendon.

**MATERIALS AND METHODS**

This was a case-control study of 30 subjects admitted to Hasan Sadikin Hospital, Bandung, Indonesia from January to September 2020. Target population is diabetic foot ulcer patients with indication for surgery such as debridement or deformity correction including Achilles tendon lengthening. Achilles tendon lengthening procedures were performed by Z-lengthening in open manner to facilitate the tendon specimen collection. Study group consists of diabetic foot ulcer patients with Achilles tendon contracture, and control group consists of diabetic foot ulcer patients without Achilles tendon contracture. We reckoned the Achilles tendon contracture if the ankle dorsiflexion was less than 10° with the knee flexed as described in a definition of equinus (12). Subjects were taken in accordance to inclusion and exclusion criteria and selected by consecutive sampling. Demographic characteristics and other information were extracted from the electronic medical records. This study was conducted ethically according to international standards as described by Padulo et al. (2018) (13).

Inclusion criteria for study group included: 1) confirmed type 2 diabetes mellitus, 2) incur foot ulceration less than 4 weeks onset, 3) sustain indication for surgery, 4) present Achilles tendon contracture, and 5) age not less than 18 years old. Inclusion criteria for control group is the same for criteria number 1, 2, 3 and 5. The distinction between both groups is at number 4, which was without Achilles tendon contracture. Exclusion criteria for both groups consisted of 1) prior ankle deformity due to congenital disease or trauma, 2) prior Achilles contractures attributed to scarring, 3) any medical comorbidities causing drop foot e.g., spinal problem, 4) patient with contraindication for surgery, and 5) patient who refuse to participate in the study.

Demographic data and related clinical characteristics were collected, including body mass index (BMI) and HbA1c levels. Independent variable in this study was TGF-β1 in Achilles tendon, analysed semi-quantitatively using immunohistochemical studies by an experienced histopathologist. Dependent variable was the contracture of Achilles tendon, concluded from ankle range of motion measurement using a goniometer with 90° knee joint flexion and expression of fibronectin, a glycoprotein which is normally present in ECM and plasma with thrombotic, inflammatory, angiogenic, and fibrogenic functions. Fibronectin was observed for its crucial role in cell adhesion, growth, migration, and differentiation (14-16).

**Sample Collection and analysis**

During the surgery, a 5 mm × 5 mm × 5 mm specimen of the Achilles tendon was obtained from each patient at the mid-substance (figure 1). Immunohistochemical analyses of TGF-β1 and fibronectin were performed using the avidin-biotin complex method. The specimens were fixed in neutral buffered formaldehyde and processed into paraffin wax by standard histological methods prior to immunostaining. Three microns thick sections were cut and placed, then dried overnight. The sections were incubated
with the primary antibodies against TGF-β1 and fibronectin for 1 hour in a humidity chamber. Biotin-labelled secondary antibodies were utilized for 7 minutes at 45 °C. The streptavidin-horseradish peroxidase detection system was then applied to the capillary channels. After drainage, the tissue sections were ready for the chromogen reaction with 3-amino-9ethyl carvazole. The sections were counter-stained with hematoxylin subsequently. The specimens were reviewed by an expert histopathologist. The stained slides were scanned at low power view. Cytoplasmic staining of TGF-β1 was scored by the percentage of positive cells (0: < 10%, 1: 10-25%, 2: 26-50%, and 3: > 51%) (17). Assessment of fibronectin staining included initial low power view and subsequent high-power observation. The observations were graded according to the following pattern: negative staining (0), focal weak staining (1 +), intense patchy staining (2 +), and intense diffuse staining (3 +).

Statistical analysis
Demographic and clinical characteristics were summarized in frequencies and percentages for categorical variables and in appropriate measures of central tendency and dispersion for continuous variables. Linear regression analysis was used to examine the associations between selected variables and outcomes of interest (development of Achilles tendon contracture). A p-value was less than 0.05 was considered to be statistically significant. All statistical analyses were performed using IBM SPSS Statistics for Windows, version 25 (IBM Corp., Armonk, N.Y., USA).

Ethics permission
This study was conducted after the ethical clearance had been granted from the Research Ethics Committee of Universitas Padjadjaran (Institution Review Board No. 00008626), No.780/UN6.KEP/EC/2019. Ethical aspect was applied to all subjects, including respect for person, beneficence, non-maleficence, and justice. The copy of ethical approval would be available upon request.

RESULTS

Clinical characteristics
The 15 patients presenting Achilles tendon contracture in the case group included 8 men and 7 women aged from 51 to 72 years (mean age: 63.13 ± 6.91 years). The 15 patients in the control group had diabetic foot without Achilles tendon contracture, including 6 men and 9 women aged from 46 to 68 years (mean age: 57.2 ± 6.07 years). BMI mean in case and control group were 26.88 ± 4.02 kg/m² and 24.54 ± 4.87 kg/m², respectively. HbA1c level median were similar, specifically 7.8% (range 5-14) in case group and 7.8% (range 5.6-14) in control group.

Immunohistochemical findings
Each slide was reviewed by an expert histopathologist and scored in areas with the highest score based on the scoring system disregarding the dimensions of the stained areas (table I):
1. TGF-β isoforms: the TGF-β expression score, as illustrated in figure 2, was significantly higher in the case group than in the control group (p = 0.025). The median score was 2 (+2) in the control group versus 1 (+1) in the control group.
2. Fibronectin: with regard to fibronectin expression (figure 3), four types of expression patterns were interpreted. Most common appearance found in case group was intense diffuse staining (11/15), in contrary with 0/15 in the control group.

Determinant analysis
The results from logistic regression analysis on the factors associated with Achilles tendon contracture and increased fibronectin expression are presented in table II. Among the tested variables, age and TGF-β1 expression score were significantly associated with the contracture (p = 0.036 and p = 0.031, respectively), while sex, BMI, and HbA1c level were not.
**DISCUSSION**

The main characteristics of diabetes mellitus is hyperglycemia. Persistent overnutrition creates a steady level of high blood glucose that is toxic to macrovascular and microvascular systems. Skin and soft-tissue infections are of particular concern in patients with diabetes mellitus, especially those with comorbid peripheral vascular disease (18, 19).

One possible cause of wound healing defects in diabetes patients has been associated with altered biology of bone marrow-derived endothelial progenitor cells. Pathological analysis has revealed abnormal microvessels that can be cuffed with collagen, laminin, fibronectin, or fibrin (20). Altered immune function is one potential effect in diabetic patients. Changes in leucocyte function figure prominently...

and are believed to result from hyperglycemia (19). Decrease of sensation and increased sensory phenomena are also an important major expressions of varieties of diabetic polyneuropathies that contribute to foot ulceration due to loss of protective sensibility to external pressure or trauma (21). Chronic non-healing ulcers are frequently observed at pressure points of the lower extremities (20). Soft tissue plantar to the forefoot is normally subjected to vertical ground reactive and shear forces (4, 22). In those cases in which propulsive phase pronation is great, minute haemorrhages develop in the skin at points of the greatest concentration of force. Limited joint mobility may predispose the diabetic foot to ulceration by producing high plantar pressure during gait. Equinus is the primary mechanical common denominator that leads to the majority of acquired non-traumatic foot and ankle problems by indirect leveraged means as well as direct forces along the posterior/plantar chain (23). Combination of high plantar pressures and sensory neuropathy has been well linked to plantar ulceration. The management of limited joint mobility resulting from tendon contracture included non-operative by regular stretching, and operative such as tendon lengthening. Bezerra et al. reported that the exercise protocol shown to be possible to prevent the progression of diabetic tendon stiffness and reduce blood glucose levels in some animal during the experiments (24).
The pathogenesis of limited joint mobility is complex and multifactorial, including angiopathy and the correlation with AGEs accumulation due to hyperglycemia (25). All the above are the predispositions of diabetic foot ulceration. Notwithstanding, not all the diabetic patients present plantar ulcerations. Certain comorbidities are considered play a role in pathogenesis of diabetic foot ulceration.

This study found no significant association between HbA1c level and Achilles tendon contracture. The finding was counterintuitive because higher HbA1c level would be expected to exhibit the highest risk of developing complications including tendon contracture. Predominantly, diabetics is still considered as etiological factor of Achilles equinus contracture. However, chronic hyperglycemia and subsequent AGEs accumulation seems not to be the sole source of fibrosis of the affected tendons.

ECM turn-over is characterized by a balance between matrix formation and matrix degradation. AGEs is not the sole cause of ECM turn-over. Factors that regulate ECM formation include multiple forms of growth factors such as TGF-β1. TGF-β is generally accepted to be the main pro-fibrotic factor in diabetic nephropathy (11). Diabetic environment up-regulated TGF-β1 expression and bioactivity in glomerular mesangial and proximal tubule cells (7, 26). Certain comorbidities has been known to affect TGF-β expression, for example cigarette smoking, in which sustained oxidative stress induces a chronic inflammation and cause further release of active TGF-β1 (27).

TGF-β is a family of growth factors involved in a number of essential cellular functions and contributes to the pathogenesis of tissue fibrosis in most organs (28). High glucose levels and mechanical stretch, particularly in a cyclic fashion, increases production of TGF-β by mesangial cells and vascular smooth muscle cells (29). Similarly, fluid shear stress, as would be induced by mechanical loading, increased production of TGF-β by cultured osteoblasts. Extracellular signalling molecules that act to increase TGF-β production include angiotensin II and thromboxane, as shown in diabetic nephropathy (11). Stimuli that activate latent TGF-β include plasmin, thrombospondin, and reactive oxygen species (28).

The three isoforms of TGF-β (TGF-β1, β2, and β3) are secreted as inactive latent precursors that require activation prior to binding to the TGF-β receptors (30). TGF-β1 and 3 play essential roles in cell proliferation and differentiation, immune response, angiogenesis, and tissue repair. While TGF-β1 promotes wound healing, it may promote fibrosis when checked. In contrast, TGF-β3 may have an anti-fibrotic role in wound healing.

Identification of TGF-β1 as a key factor in the cascade of Achilles tendon contracture development and thorough understanding of its regulation will contribute into not only prevention but also treatment the contracture. Neutralizing the actions of TGF-β with highly specific monoclonal antibodies or with application of antisense technology can effectively prevent the fibrosis (11). One approach is to reduce TGF-β gene expression, either by suppressing the initiation of gene transcription or by altering mRNA stability. TGF-β mRNA expression is reduced by anti-sense oligonucleotide, interferon α, and anti-oxidants such as α-tocopherol (28). Another approach directly targets circulating TGF-β. Thus, administration of anti-TGF-β antiserum at the time of induction of experimental mesangial proliferative glomerulonephritis suppresses the accumulation of ECM and histologic manifestation of disease (28, 31).

Along with TGF-β1 expression, age was found to be a significant determinant of contracture in this study. The common use of the terms “decrease flexibility” or “increased stiffness” in association with the decrease in maximal passive dorsiflexion ROM implies that shorten calf muscle-tendon unit may become stiffer with aging, even in active adults without related pathologies (32). Prior studies has also reported some contributing factors to increased TGF-β1 level, such as the duration of cigarette smoking (33).

This study has limitations. We identified our patients based on the surgery indication, thus, other than small sample size we cannot account for patients without wound who had not presented for evaluation. We were unable to adjust our analyses for multiple factors such as vascular status, neuropathic severity, and smoking habits due to relatively small group sizes. The more objective parameters should be done to assess the clinical examination of tendon contracture, for example, using ultrasound techniques as described by Kuo et al. (34). However, this study may provide the framework to define the diabetic foot management algorithm, particularly regarding the role of TGF-β1 in Achilles tendon contracture pathogenesis.

The results of this study revealed that TGF-β1 play a role in the pathogenesis of Achilles tendon contracture in diabetic foot other than chronic hyperglycemia. The involvement of TGF-β1 in contracture or tissue fibrosis suggest that TGF-β1-mediated pathways may be one of therapeutic targets for diabetic foot managements. This study research can contribute a more detailed understanding of the role of TGF-β1 in pathogenesis of equinus contracture of Achilles tendon in diabetes population, which leads to the development of plantar ulcerations. Further studies to identify the determinants of increasing TGF-β1 expression and tissue level, can be performed based on this study. Clinical benefits of this study include yielding information on significance of increasing TGF-β1 activity in Achilles tendon contracture.
tures, thus the clinician can identify and control the causative factors, as well as the therapeutic interventions.
